

SPECTACLED BEAR SKULL

These members of the family Ursidae are carnivorous mammals. Today, spectacled bears survive only in South America. Like pandas, they are on the verge of becoming extinct. This Andean bear fossil, in which all the details of the skull have been preserved, reveals that this species has remained the same at all times. The tooth structure, eye sockets, jaw structure etc. of this animal that lived 85 million years ago all reveal that spectacled bears have remained unchanged for tens of millions of years, in other words, that they never evolved. The fact revealed by this and other fossil discoveries is that Creation, not blind coincidences, represents the origin of living things. <https://www.harunyahya.info/it/articoli/spectacled-bear-skull-97041>
